1 ЗАВДАННЯ

1. Побудуйте алгоритм статистичного аналізу тексту та визначте характеристики випадкової величини «довжина слова в символах» з використанням ForkJoinFramework. 20 балів. Дослідіть побудований алгоритм аналізу текстових документів на ефективність експериментально. 10 балів.
2. Реалізуйте один з алгоритмів комп'ютерного практикуму 2 або 3 з використанням ForkJoinFramework та визначте прискорення, яке отримане за рахунок використання ForkJoinFramework. 20 балів.
3. Розробіть та реалізуйте алгоритм пошуку спільних слів в текстових документах з використанням ForkJoinFramework. 20 балів.
4. Розробіть та реалізуйте алгоритм пошуку текстових документів, які відповідають заданим ключовим словам (належать до області «Інформаційні технології»), з використанням ForkJoinFramework. 30 балів.

2 ВИКОНАННЯ

2.1 Аналіз текстів. Бібліотека Apache OpenNLP

Оскільки я цікавлюся машинним навчанням та аналізом текстів, то виконував перше та третє завдання комп'ютерного практикуму за допомогою бібліотеки Apache OpenNLP.

Apache OpenNLP спеціалізується на NLP — Natural Language Processing, що дуже допоможе токенизувати неструктурований природний текст, який містить розділові знаки, скорочення, аббревіатури тощо.

Тому імпортуємо у Maven відповідні бібліотеки.

```
<dependency>
  <groupId>org.apache.opennlp</groupId>
  <artifactId>opennlp-tools</artifactId>
  <version>2.2.0</version>
</dependency>
<dependency>
  <groupId>org.apache.opennlp</groupId>
  <artifactId>opennlp-dl</artifactId>
  <version>2.2.0</version>
</dependency>
<dependency>
  <groupId>org.apache.opennlp</groupId>
  <artifactId>opennlp-uima</artifactId>
  <version>2.2.0</version>
</dependency>
<dependency>
  <groupId>org.apache.opennlp</groupId>
  <artifactId>opennlp-morfologik-addon</artifactId>
  <version>2.2.0</version>
</dependency>
<dependency>
  <groupId>org.apache.opennlp</groupId>
  <artifactId>opennlp-brat-annotator</artifactId>
  <version>2.2.0</version>
</dependency>
```

Для роботи з бібліотекою необхідно завантажити моделі лематизації, розділення речень, токенизації та визначення частин мови.

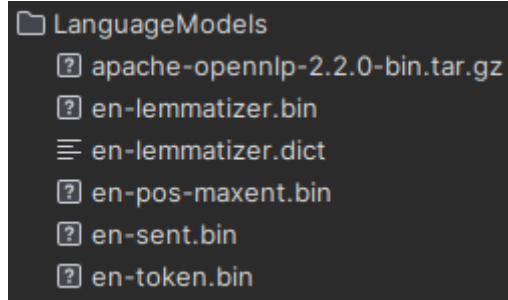

Рисунок 2.1.1 - Лінгвістичні моделі

Розшифрую значення слова “лематизація” — по-простому це перетворення певного слова до його початкової форми, тобто: “слова” — “слово”, “зроблю” — “зробити”, “гарна” — “гарний” тощо.

За допомогою лематизації можна знаходити схожі слова, що потім використаю у третьому завданні.

2.2 Логування. Бібліотека log4j2

Зазвичай для кращої обробки результатів, процесу дебагу програми застосовують логування. У Java є досить популярна бібліотека log4j. Імпортуємо її.

```
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j</artifactId>
  <version>2.20.0</version>
</dependency>
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-api</artifactId>
  <version>2.20.0</version>
</dependency>
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-core</artifactId>
  <version>2.20.0</version>
</dependency>
<dependency>
  <groupId>org.apache.logging.log4j</groupId>
  <artifactId>log4j-jul</artifactId>
  <version>2.20.0</version>
</dependency>
```

Для кожного завдання існують логи, де можна побачити результати⁹ ефективності алгоритмів.

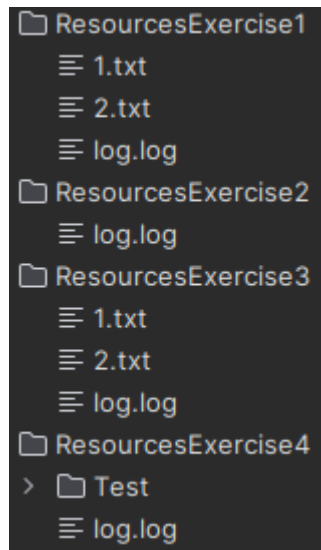

Рисунок 2.2.1 - Логи та допоміжні файли для кожного із завдань

2.3 Перше завдання

Розглянемо структуру проєкту.

Рисунок 2.3.1 - Структура проєкту

TextAnalyzer — клас, що відповідає за зчитування файлів, розбиття їх на речення та токенизацію речень.

AverageLengthForkJoin — дочірній клас RecursiveTask, що перевизначає метод compute а повертає пару кількості токенів та їхньої суцільної довжини.

AverageLengthTester — клас, який перевіряє роботу однопотокової та багатопотокової версій алгоритму.

Поглянемо на результати ефективності, що знаходяться у ResourcesExercise1/log.log .

[FORK JOIN EFFICIENCY: 1.0625]

Як бачимо, чим більший розмір файлу, тим ближче ефективність наближається до 1. Це пов'язано з тим, що моделі важкі та забирають сильно оперативну пам'ять, тому існує лише один екземпляр моделі, який синхронізовано використовують декілька потоків, що знижує швидкість алгоритму.

2.4 Друге завдання

Розглянемо структуру проєкту.

ExecutorAlgorithm та ForkJoinAlgorithm - стрічковий алгоритм множення матриць за допомогою як ForkJoinFramework так і Executor.

ExecutorAlgorithmTask та ForkJoinAlgorithmTask — дочірні класи Runnable та RecursiveAction відповідно, що розбивають обрахунок алгоритмів на частини.

AlgorithmTester — клас для тестування ефективності алгоритмів.

3 ВИСНОВОК

Під час лабораторної роботи опрацювали розробку паралельних програм з використанням пулів потоків, екзекуторів та ForkJoinFramework.

Для вирішення першого та третього завдань була використана бібліотека обробки природної мови Apache OpenNLP, що проводила токенизацію речень, а за допомогою ForkJoinFramework токени оброблювалися у багатопотоковому середовищі. Результати до першого завдання в ефективності алгоритму не є показовими, оскільки ледь перевищують 1. Це можна пояснити тим, що токенизація доволі складний процес, і вона проводилася в одному потоці, оскільки модель є важкою і завантажує мій комп'ютер. Щодо третього завдання, то ефективність стало тримається у межах 1.5 до 1.9, що є відчутним приростом у швидкості.

У другому завданні є версії використання з екзекуторами та ForkJoinFramework.

У четвертому завданні бачимо суттєвий приріст швидкості, що досягає 6 разів у порівнянні з однопотоковою рекурсивною версією.

Отже, для програміста суттєво знати шляхи для реалізацію паралельних програм, оскільки вони можуть суттєво збільшити швидкість виконання операцій.
